

Public Eyes, Private Pace

Remediation Timing Shows No Gap Between the Living Dashboard's Public and Internal-Only Displays

Mirela Hanke · Renke Sabel — School of Continuous Improvement

Background

The Living Dashboard exposes select remediation-status tiles University-wide on the premise that visibility accelerates a fix. Whether a watched tile actually closes faster than an identical one nobody outside the unit can see has not itself appeared on the dashboard.

Aims

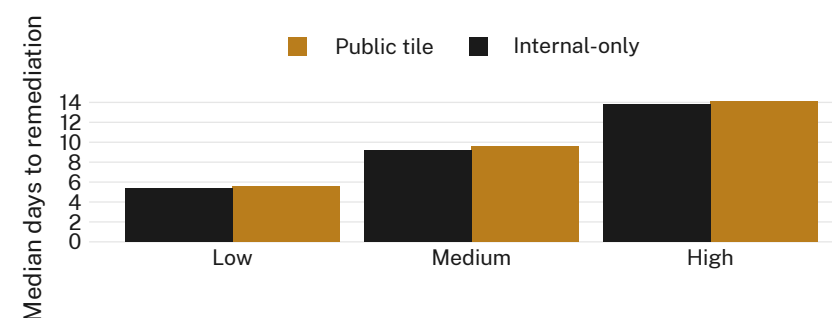

- Compare median time-to-remediation between public and internal-only display conditions.
- Test whether severity tier moderates any visibility effect.
- Establish whether the public tile's operating rationale survives its own remediation log.

Methods

- n = 214 flagged issues, both schools, 11-month window (Aug 2025–Jun 2026)
- issues randomly assigned to public or internal-only tile at flag time; severity tier held constant across arms
- remediation clock stopped at unit's own closure sign-off; thresholds pre-registered, none adjusted post hoc

Results

Median remediation time is statistically indistinguishable between arms across all three severity tiers (9.4 vs 9.1 days overall, n.s.). The gap the public tile was commissioned to close does not appear in its own timing record.

Median days to remediation by severity tier, 1 Aug 2025–30 Jun 2026 (n = 214): public and internal-only arms differ by under half a day in every tier.

Discussion & conclusions

Visibility changes who can see a delay, not how quickly it closes. Next: the Indicator Commons' review-flagged items, where a visibility premium is assumed rather than measured.

“The tile that’s watched moves no faster than the one that isn’t.”

Median remediation time differs by under half a day across every severity tier (n = 214, Aug 2025–Jun 2026).
