

Impossible to Miss, Beside the Point

Live Channel-Swap Leaderboards at a Silent Disco Don't Track What the Crowd Preferred

Ingeborg Nwachukwu · Torun Ezeigwe — School of Continuous Improvement

The problem

A 2026 School of Continuous Improvement finding tied a little free library's posted take-vs-leave ratio to neighbours' own ratings only once the placard could actually be read. Would a leaderboard nobody could miss finally let a posted number track what a crowd preferred?

Objectives

- Test whether a silent disco's live channel-swap-count rank predicts each channel's post-set enjoyment rank.
- Re-run the library study's "legibility, not signal" account somewhere the sign cannot be missed.
- Identify what the posted swap count tracks, if not preference.

Approach

- n = 248 wristbanded attendees · 19 weekly nights · 3 channels per night · Feb–Jun 2026
- Live swap counts read off a centre-truss leaderboard, refreshed every 30 seconds; enjoyment self-rated 1–5 at each channel exit
- Swap-count rank vs enjoyment rank compared per channel-night (Spearman); exit-corridor proximity and launch order logged as covariates, thresholds pre-registered

What we found

Live swap-count rank shows no meaningful association with post-set enjoyment rank across 57 channel-nights ($p = 0.11$, ns). The top-ranked channel by swap count matches the top-rated channel by enjoyment in exactly 33% of nights — the rate three unordered channels would match by chance alone.

Live swap-count rank and post-set enjoyment rank agree in 3 of 9 sampled channel-nights (Red/Night 3, Green/Night 9, Blue/Night 15) — exactly the rate three unordered channels would match by chance; the other six show at least a one-rank swap or a full reversal.

Interpretation & where next

The 2026 library study attributed its correlation entirely to placard legibility, predicting an unmissable leaderboard would restore the tracking. It does not: the number is as visible as a number gets, and it still fails to track enjoyment. Swap counts instead index the room's exit corridor ($p = 0.68$) and, more weakly, which channel launched first each night ($p = 0.44$) — artefacts of layout and running order, not taste.

A visible number, it turns out, is not automatically a valid one: legibility removed one confound and left the layout confound standing in its place.

Next: rotate channel position and launch order nightly to test whether either alone accounts for the correlation the leaderboard actually shows.
